## Table of contents:

(PART 0) theory of the Yarkovsky/YORP effect

(PART 1) direct measurements of Yarkovsky/YORP

(PART 2) applications to asteroid families

(PART 3) meteoroids, NEA's and resonant asteroids

Accelerations in the size-range:

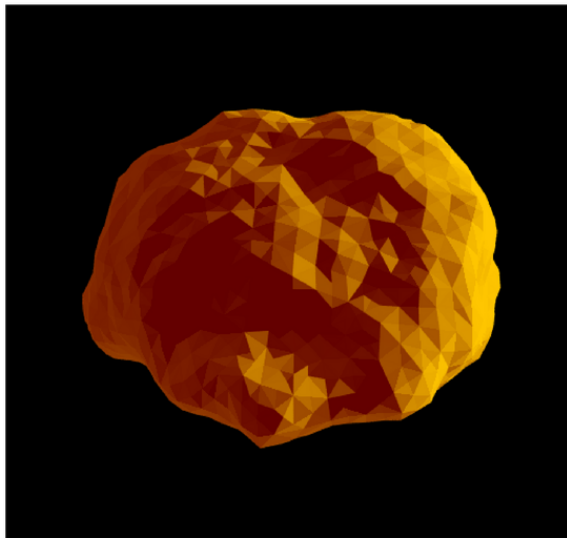

**10 cm to 10 km**

0. gravity	$GM_{\odot} \simeq 1$	$GM_{\text{pl}} \simeq 10^{-3}$ $GM_{\text{ast}} \lesssim 10^{-9}$
1. <b>Yarkovsky/YORP effect</b>	<b><math>10^{-7}</math> to <math>10^{-11}</math></b>	
2. radiation pressure	$10^{-6}$ to $10^{-11}$	
3. Poynting-Robertson drag	$10^{-10}$ to $10^{-15}$	
4. solar wind	“too small”	
5. Lorentz force	:	
6. plasma drag		

- radial pressure vs. drag & long-term accumulated effect

## What do we need to calculate Yarkovsky/YORP?

- orbit, size and shape, spin axis orientation and period, mass, density of surface layers, albedo, conductivity, ...
- often: thermal parameters as free & collective studies

## Yarkovsky/YORP — state-of-the-art theory

- analytical **spherical** linearised solution of the HDE
- numerical **1-dimensional** non-linearised approximation for irregular shapes ← not valid for small meteoroids!
- recent developments: **analytical** calculation of **YORP** for shapes slightly different from spheres (Nesvorný & Vokrouhlický, submitted)

also Scheeres (2007, in press): semianalytic YORP theory

- future: full numerical 3-D solution of the HDE  
⇒ YORP on small bodies, statistics for  $\approx 100$  shapes

## PART 1

Direct measurement of Yarkovsky (Chesley *et al.*, 2003):

- radar ranging to (6489) Golevka  $\Rightarrow$  semimajor axis drift

- thermal conductivity 0.01 W/K/m  $\leftarrow$  in agreement with infrared photometry (Delbó *et al.* 2003)
- another case: long arc of 1992 BF (Chesley *et al.*, 2006)

## Direct measurement of YORP:

- lightcurves (or radar)  $\Rightarrow$  rotational phase shift
- Lowry *et al.* (2007), Taylor *et al.* (2007): (54509) YORP = 2000 PH<sub>5</sub>, radar shape, size 100 m  $\rightarrow$  1 ms/yr
- Kaasalainen *et al.* (2007): (1862) Apollo, shape from LC inversion, size 1.4 km  $\rightarrow$  period change 4 milliseconds/yr

# PART 3

## Asteroid families:

(Bottke *et al.*, 2001; Vokrouhlický *et al.*, 2006)

- “Bracketing” by resonances
- “Crossing” weaker MMRs
- “Trapping” in secular resonances

→ Eos family  
as an example

## Bimodal obliquity distribution in Koronis family (Slivan *et al.*, 2003):

- prograde group: periods 7.5–9.5 h, obliquities 42°–50° and similar ecliptic longitudes within 40°
- retrograde group:  $P < 5$  h or  $> 13$  h,  $\gamma \in (154^\circ, 169^\circ)$   
 $\Rightarrow$  collisions cannot produce this!

Spin state model (Vokrouhlický *et al.*, 2003):

- solar torques & YORP thermal torque

- prograde group: (I) YORP driven evolution to asymptotic state & (II) capture in spin-orbit resonance  $s_6$  (precession rate  $\simeq 26''/y = -s_6$ )  $\Rightarrow$  parallelism in space

## “Eared” families (Vokrouhlický *et al.*, 2006):

- ‘V’-shape in the  $(a, H)$  plane
- outliers  $\Leftrightarrow$  probable interlopers

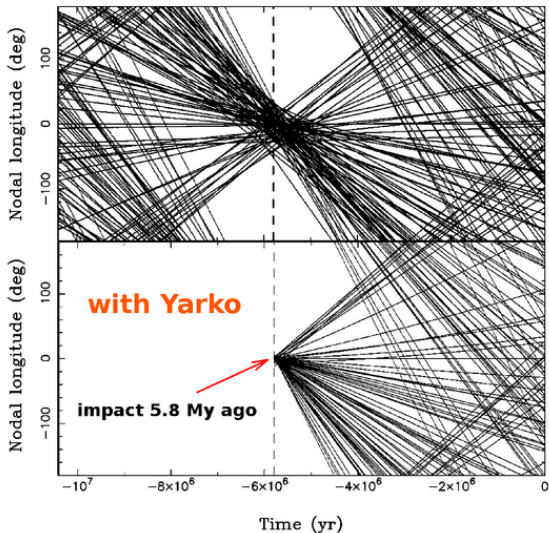

- problem: unknown *initial* spread
- “eared family” (overdensity of small members at extreme values of the semimajor axis)  $\Leftrightarrow$  YORP effect fingerprint!

- best-fit family evolution model:
- initial dispersion  $\sim 1/2$  of observed

- $V = 24_{-12}^{+6}$  m/s  $\Rightarrow$  small ejection velocity
- $c_{\text{YORP}} = 0.6_{-0.4}^{+1.4}$   $\Rightarrow$  YORP important
- $T = 238_{-23}^{+52}$  My  $\Rightarrow$  young age
- $K = 0.005$  W/m/K  $\Rightarrow$  regolith

## Convergence of angles in Karin cluster (Nesvorný & Bottke, 2004):

- both  $\Omega$ ,  $\varpi$  converge much better with Yarkovsky!
- another case: Veritas family 8.2 Myr ago  $\rightarrow$  dust bands and  $^3\text{He}$  in sea-floor sediments (Farley *et al.* 2006)

## PART 3

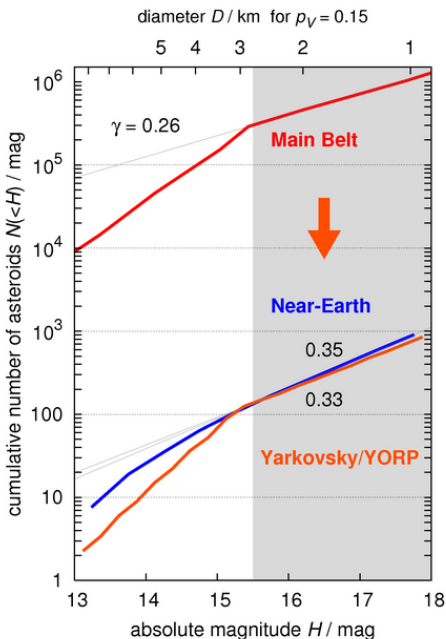

### Meteorite transport from the Main Belt:

(Farinella *et al.*, 1998; Vokrouhlický & Farinella, 2000; Bottke *et al.*, 2000) ← **no YORP here!**

- long Cosmic Ray Exposure ages of meteorites
- CRE's of iron meteorites  $10\times$  longer than of stones

## Delivery of Near-Earth Asteroids (Morbidelli & Vokrouhlický, 2003):

- observations of NEAs:
  1. removal rate:  $\sim 200$  bodies ( $> 1$  km) per My
  2.  $H$  distribution
  
- the same basic scenario as for meteorites:
  1. Yarko/YORP flux into the resonances:  $150\text{--}200 \text{ My}^{-1}$
  2. slope change

- La Spina *et al.* (2004): excess of retrograde NEAs  
 ← consistent with Yarkovsky-driven transport from the MB via  $\nu_6$  and J3/1 resonances

## Binaries and YORP?

- Ostro *et al.* (2006): radar imaging of (66391) 1999 KW<sub>4</sub>

- equatorial hill ← mass shedding?
- Kaasalainen *et al.* (2007): (1862) Apollo will reach critical  $P \simeq 2$  hours within few Myr (maybe it already did in the past  $\Rightarrow$  its small moon)
- Pravec & Harris (2006): MB binaries are similar to NEAs  $\Rightarrow$  YORP induced fission (and not tidal encounters)?

## Unstable resonant asteroids in the J2/1:

(Brož *et al.*, 2005; Roig *et al.*, 2002)

- **short-lived** ( $\sim 10$  Myr)  $\leftarrow$  neighbouring MB asteroids pushed by Yarkovsky towards the resonance:

$n_{\text{TP}}$  isosurfaces 100 and 1000 TPs / bin / 1 Gy

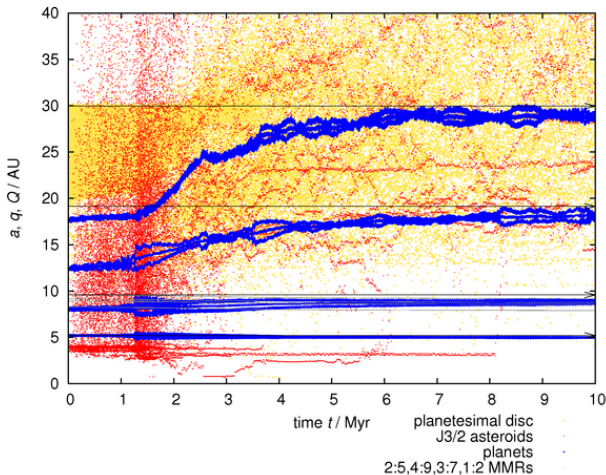

- confirmed by orbital evolution, lifetimes and SFDs

## Stable resonant asteroids in the J2/1 and J3/2:

- simple Yarkovsky injection from the MB does not work  
 ⇒ more complex evolution with **migration of planets**  
 due to planetesimal disc  $30\text{--}50 M_{\oplus}$  similar to  
 the ‘Nice model’ (Morbidelli *et al.*, 2005)

- $\sim$  half of J2/1 orbits survive ⇒ might be primordial, but...

## THE THERMAL FORCES AND TORQUES...

- almost no Hildas in the J3/2 survive Jupiter–Saturn 1:2 resonance crossing  $\Rightarrow$  must had been captured during the crossing or after (by resonance sweeping)

original population

final population

- Yarkovsky does not significantly destabilise the orbits during the following 4 Gyr evolution

## Future work:

- routine Yarkovsky/YORP detection
- systematic ages of all asteroid families, including extremely young (like Datura) and old ones (like Koronis)
- calculation of YORP on small meteoroids  
→ corresponding update of transport models
- measurement of thermal-related parameters (masses, sizes, shapes, albedos, conductivity)
- modelling of several subsequent YORP cycles
